

How long should the fiber optic cable of the terminal box be stripped

AI Overview

The fiber optic cable should typically be stripped to a minimum of 1 meter for terminal box installation, with the bare fiber itself stripped about 1.5 inches (35–40 mm) for splicing or connectorization.

Stripping the Cable for Terminal Box Installation

When preparing a fiber optic cable for a terminal box, the overall cable jacket should be stripped to at least 1 meter to provide sufficient slack and buffer for coiling inside the box and for secure splicing with pigtails. This length ensures that the cable can be properly fixed, coiled, and connected without strain, while leaving enough room for adapters and splice trays.

Stripping the Fiber Itself

After removing the outer jacket, the Kevlar strength members should be cut, and the fiber buffer should be stripped to expose the bare fiber. For most splicing or connector exercises, the bare fiber is typically stripped 1.5 inches (35–40 mm). This allows for proper cleaving and insertion into splices or connectors while minimizing the risk of fiber breakage.

Layered Stripping Considerations

For multi-layer cables, each layer—jacket, aramid yarn, and buffer—must be stripped individually to the correct length. The outer jacket is removed first, followed by the aramid yarn, and finally the buffer coating. Using a stripping template or manufacturer's guidelines is recommended to ensure precise lengths and avoid damaging the fiber.

Best Practices

Use a fiber optic cable stripper and adjust the blade depth according to the cable diameter. Clean the stripped fiber with alcohol wipes to remove debris before cleaving. Use a fiber cleaver to create a clean, perpendicular end face for optimal splicing or connectorization. Coil any remaining cable inside the terminal box to prevent strain and maintain organization. By following these specifications and best practices, you can ensure a secure, reliable, and high-performance fiber optic termination in the terminal box.
