

# The core device of a switch

## Overview

The switching engine is the core component of the switch, responsible for data forwarding and routing. It processes data packets from various ports and forwards them to the correct output ports based on destination address information. Engineered to aggregate massive volumes of data from distribution switches, it provides ultra-low latency and maximum throughput to ensure uninterrupted routing and packet. A core switch in networking serves as the high-capacity backbone, italic centralizing data flow and ensuring efficient communication between different network segments. Simply put, it's the kingpin that keeps your network humming. The layer that lies between the access layer and the core layer is known as the distribution or aggregation layer, while the backbone of the network is termed the core layer.
